

Two genomes · invented variants and identity

Example reference · reference span 4.800 Mb
A · Genome A

READ THE RINGS · Start at the top and move clockwise. There are no x/y axes; M means one million base pairs (bp).

R is the reference; letters identify comparison genomes from inner to outer. For example, 0.960 Mb is one fifth along this 4.800 Mb reference.

Outlined gaps = deletions; capped ticks = insertions; split arcs = duplications; solid arcs = inversions; ticks = single-base changes.

Arc lengths show reference spans. Insertion ticks mark positions only; their size does not indicate inserted length or direction.

Curved ribbons connect supplied duplication source and copy positions. Colours identify variant calls independently of identity shading; overlaps may hide calls.

More differences are not inherently better or worse. This figure does not establish a biological effect.

Inner dark bands are a ruler: alternating every 500,000 bp, not measurements.

Outer shading is supplied identity: darker = more matching aligned bases. Scale: light ≤90%, mid 95%, dark 100%; pale green = no score.

For example, 99% identity means about 99 of 100 aligned bases match. Higher means more similar, not better; coverage is not shown.
