

Anopheles: a published comparison of two malaria vectors

BLOCK-ORDER VIEW | Equal-width blocks; distances and lengths are not base pairs

A Conserved blocks connect different chromosome-arm arrangements

380 published blocks | five arms per species | colour follows the *An. gambiae* arm

B The same block orders in a circular view

Arc lengths count blocks; chromosomes are biologically linear

C X chromosome: changes in block order

66 blocks | 44 opposite in orientation in the source table

Reading the figure

2L in *An. gambiae* corresponds to 3L in *An. stephensi*;

3L in *An. gambiae* corresponds to 2L in *An. stephensi*.

Ribbons preserve published block order and signs.

Opposite-orientation blocks do not count inversion events.

Published stephensi physical map covers ~62% of the assembly; 32/86 mapped scaffolds had experimentally assigned orientation.

This figure illustrates comparative genome organization; it does not establish effects on malaria transmission or insecticide resistance.
